ABSTRACT

A method and system for providing a business-to-business network service for applications used by service providers is disclosed. The method and system include providing a central application capable of communicating with at least two applications over a public network, such as the Internet, and providing a repository database for storing customer information that spans more than one of the service providers. The method and system further include allowing the applications to query the repository database through the central application, thereby making the customer information accessible to each of the applications.
